Field of the Invention This invention relates to the field of processors and more particularly to branch prediction in processors. 2. Description of the Relevant Art Superscalar microprocessors achieve high performance by executing multiple instructions per clock cycle and by choosing the best available instruction to execute in each cycle. To achieve the highest possible performance, the next instruction to execute is not always the one that is next in program order. The optimal instruction to execute is the one that improves the overall utilization of the processor pipeline(s). Pipelines were devised to allow the execution of multiple instructions within the same clock cycle by using the execution units (e.g., floating point unit, adders, shifters, etc.) multiple times to execute multiple instructions in parallel. To choose the best available instruction for execution, the microprocessor refers to a branch prediction unit to determine which instruction to execute next. The branch prediction unit examines code sequences referred to as "branch prediction hints" to predict whether the branch will be taken or not. The branch prediction unit predicts the direction of the taken branch most of the time, and 09e8f5149f
